

# ***Alkali-antimonide Photocathodes for Gas-Avalanche Photomultipliers***

***A. Lyashenko, R. Chechik and A. Breskin***

*Weizmann Institute of Science, Rehovot, Israel*

*Recent review on GPMs: Chechik & Breskin NIM A595 (2008) 116*

*Summary article visible-light GPM: Lyashenko et al. JINST 4 (2009) P07005*

# Gaseous Photo-Multipliers (GPM)

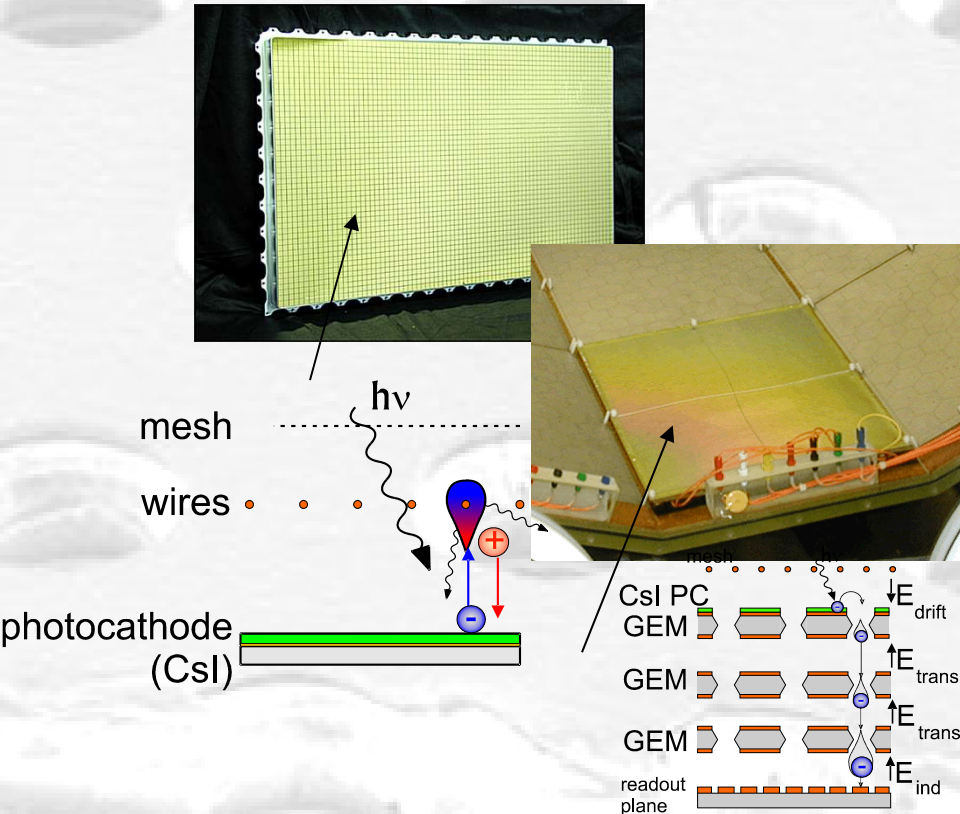

**Visible-in course**

**UV-exist:**

ALICE, HADES,  
COMPASS,  
J-LAB, PHENIX

**Motivation:**

- **large areas**, flat geometry
- operation in magnetic fields
- sensitivity to *single photons*
- **visible spectral range**
- fast (ns range)
- high localization accuracy (sub-mm range)

## Principles of GPM operation

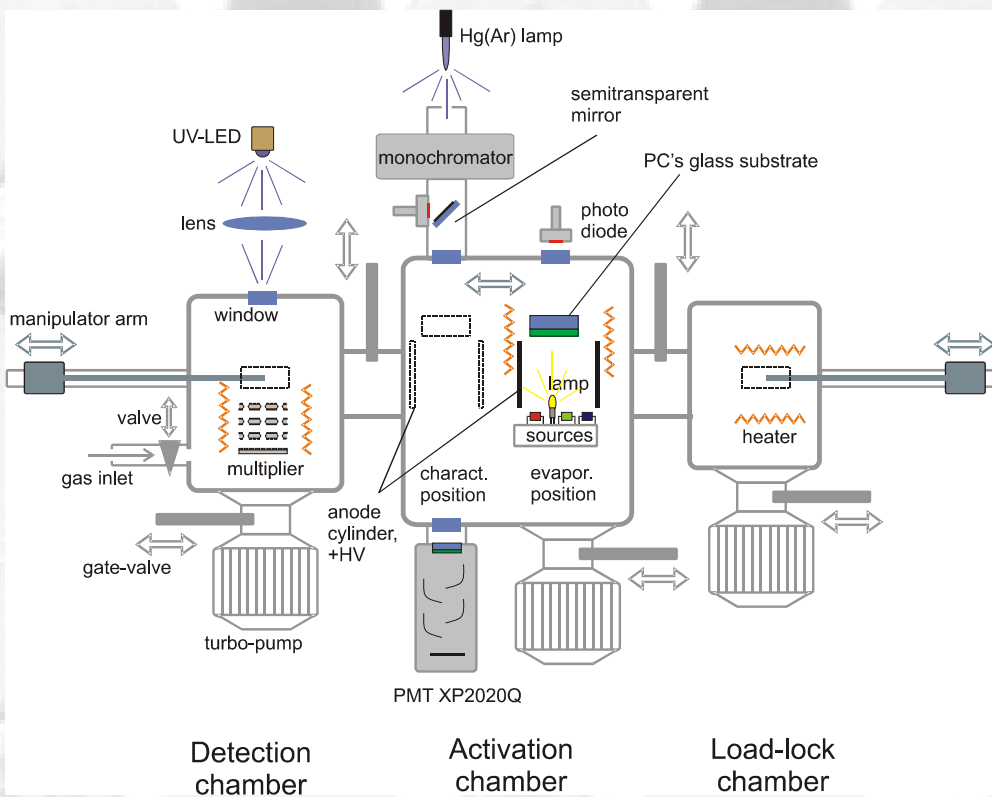

*Photoelectron emission from photocathode*

*Avalanche charge multiplication in gas*

*Signal recording*

# Multi-chamber UHV setup

- **Alkali-antimonide pc production** (*QE 20-50% @ 350-400nm in vacuum for semi-transparent PC*)

- **Hot Indium sealing** to package @130-150°C => *critical for pc*

## PC fabrication process:

- *PC substrate treatment in air*
- *PC substrate treatment in vacuum (usually baking at 270-300°C)*
- *Evaporation of alkali-metals*

*PC sensitivity*

*Long term stability*

**Designation: S-11**

**Activation steps:**

1. Evaporation of **Sb** at 180-200°C onto a substrate until it looses ~20% of its transparency
2. Exposure to **Cs** at 150-180°C until the maximum of photocurrent is reached.
3. Post-treatment if needed (removing of excess of **Cs** by baking at ~200°C)

**Activation time: 30-60 min**

**PC characteristics (typical):**

- Wavelength of max response:  $\lambda_{max} = 370-400nm$
- Luminous sensitivity:  $100-120\mu A/lm$
- Responsivity at  $\lambda_{max}$ :  $65-75mA/W$
- QE at  $\lambda_{max}$ : 20-25%
- Dark emission current at 25°C:  $\leq 0.1fA/cm^2$
- Surface resistance at 25°C:  $3 \cdot 10^7 Ohm/square$

**Large area: YES**

## Photocathodes: $K_2CsSb$

### Activation steps:

#### One possibility:

1. Evaporation of **Sb** at 180-200°C onto a substrate until 20% of transparency is lost
2. Exposure to **K** at 160-200°C until the maximum of photocurrent is reached (formation of  $K_3Sb$  PC).
3. Repetitive (yo-yo) exposure to **Cs** & **Sb** at 180-225°C until the maximum of photocurrent is reached.

#### Another possibility:

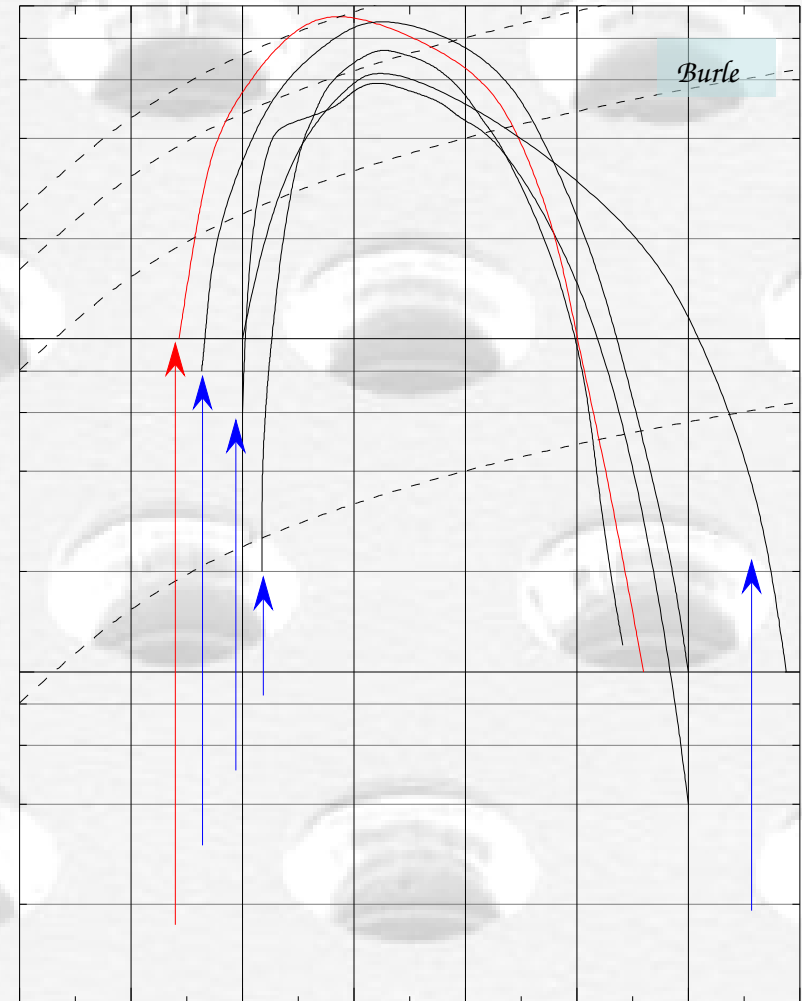

So called co evaporation

### PC characteristics (typical):

- Wavelength of max response:  $\lambda_{max} = 380-420nm$
- Luminous sensitivity: 70-100  $\mu A/lm$
- Responsivity at  $\lambda_{max}$ : 100  $mA/W$
- QE at  $\lambda_{max}$ : >30%
- Dark emission current at 25°C:  $\leq 0.01 fA/cm^2$
- Surface resistance at 25°C:  $6 \cdot 10^9 Ohm/square$

**Features:** Very high surface resistance

**Large area:** YES, needs a conductive layer

## Photocathodes: $\text{Na}_2\text{KSb}$

### Activation steps:

1. Evaporation of **Sb** at 180-200°C on substrate until it loses 20% of its transparency
2. Exposure to **K** at 160-200°C until maximum photocurrent reached ( $\text{K}_3\text{Sb}$ ).
3. Exposure to **Na** at ~220°C until the rise of PC current start slowing down\*.
4. Alternating addition of **Sb** and **K** at ~160-180°C until maximum photocurrent reached.

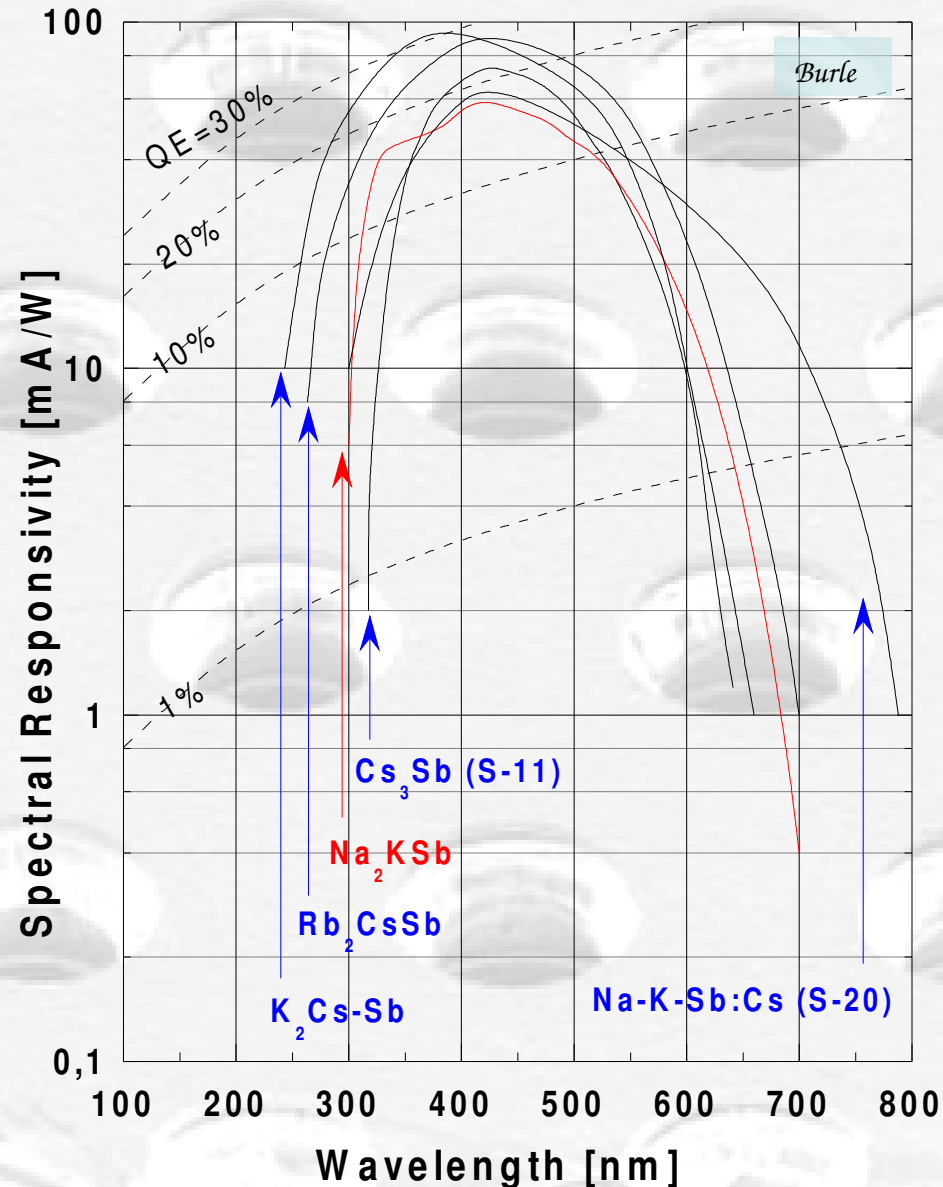

\* Simultaneous evaporation of **K** and **Na** is possible

### PC characteristics (typical):

- Wavelength of max response:  $\lambda_{\text{max}} = 380-410\text{nm}$
- Luminous sensitivity: 65-80  $\mu\text{A}/\text{lm}$
- Responsivity at  $\lambda_{\text{max}}$ : 64  $\text{mA}/\text{W}$
- QE at  $\lambda_{\text{max}}$ : 19-21%
- Dark emission current at 25°C:  $\leq 0.0001\text{fA}/\text{cm}^2$
- Surface resistance at 25°C:  $2 \cdot 10^6\ \Omega/\text{square}$

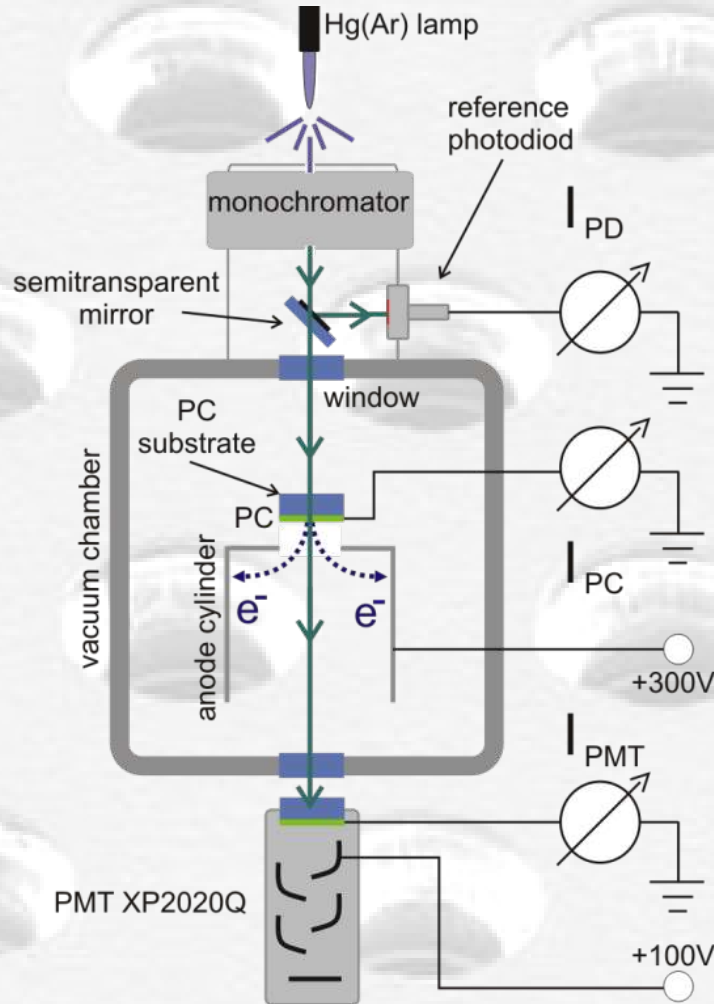

**Features:** Outstanding temperature stability (up to 200°C), lowest dark current

**Large area:** YES, but production is rather complicated, QE < other Bi-alkali.

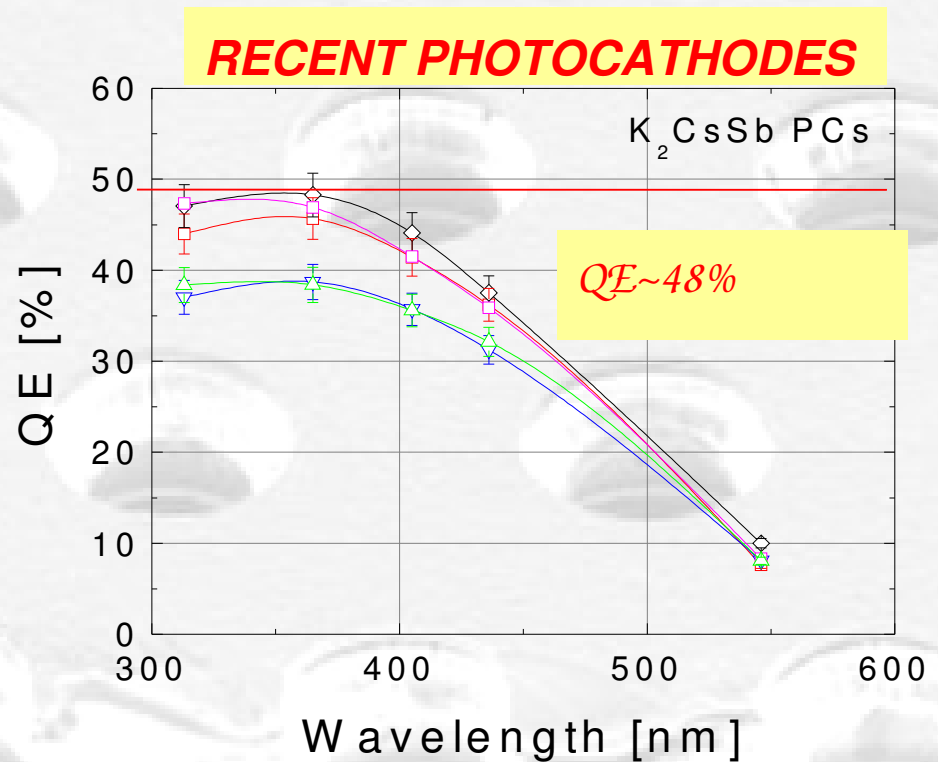

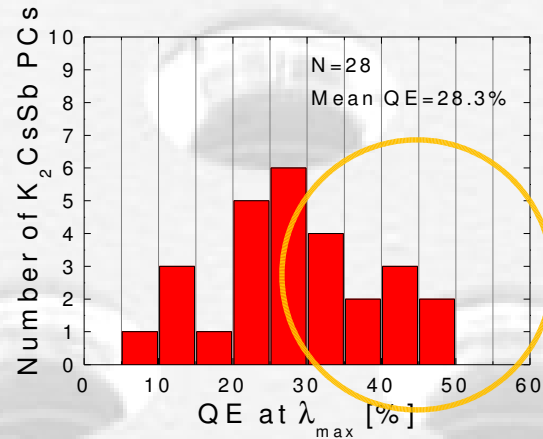

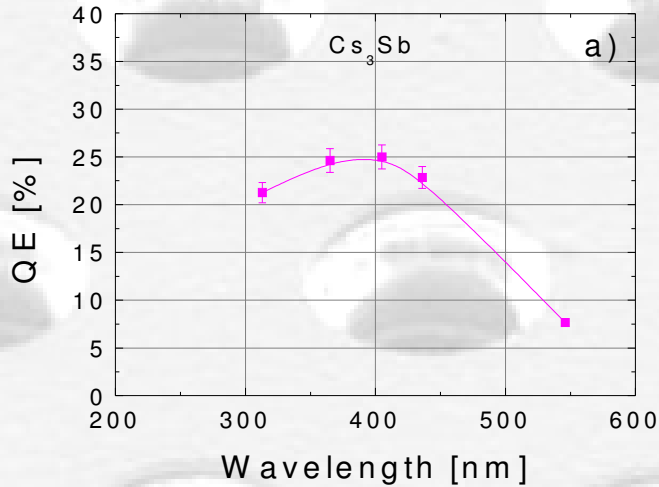

## PC characterization

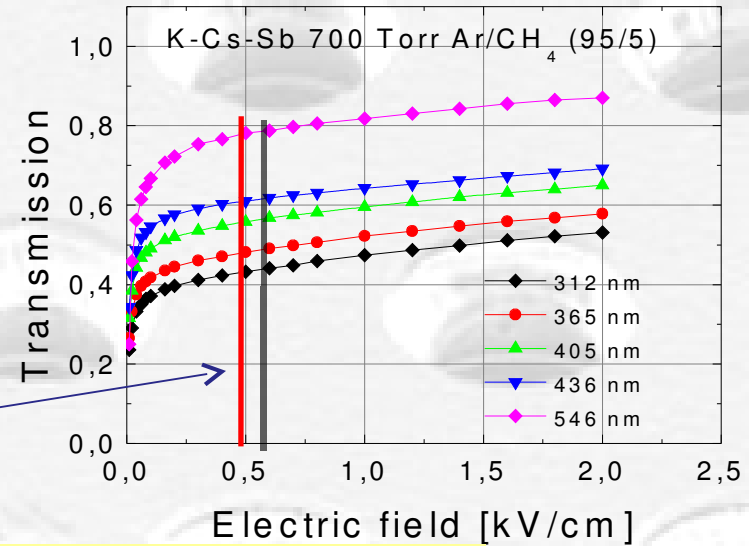

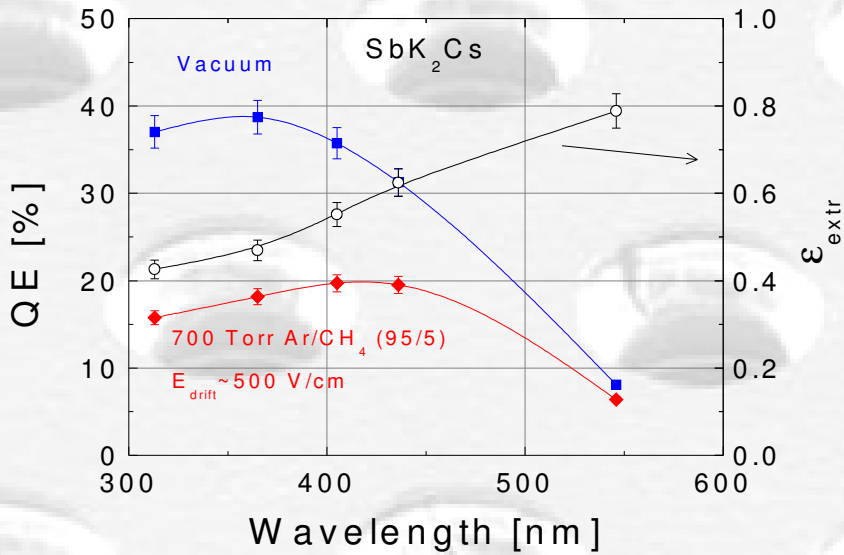

$$QE(\lambda) = \frac{I_{PC}(\lambda) - I_{PC}^{dark}(\lambda)}{I_{PMTtrans}(\lambda) - I_{PMTtrans}^{dark}(\lambda)} \cdot \frac{I_{PDtrans}(\lambda) - I_{PDtrans}^{dark}(\lambda)}{I_{PD}(\lambda) - I_{PD}^{dark}(\lambda)} \cdot T_W(\lambda) \cdot QE_{PMT}(\lambda)$$

# QE of alkali-antimonide photocathodes

# Photoelectron extraction from bi-alkali PC into gas

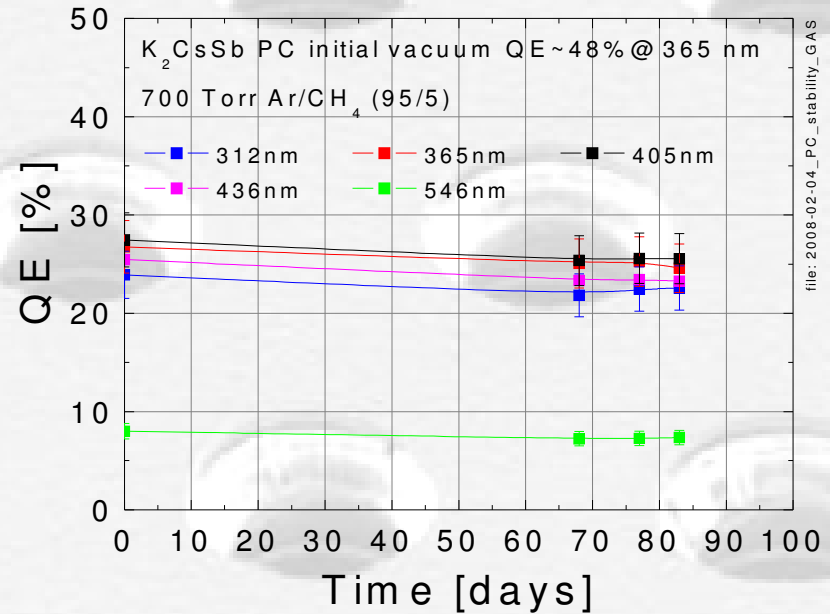

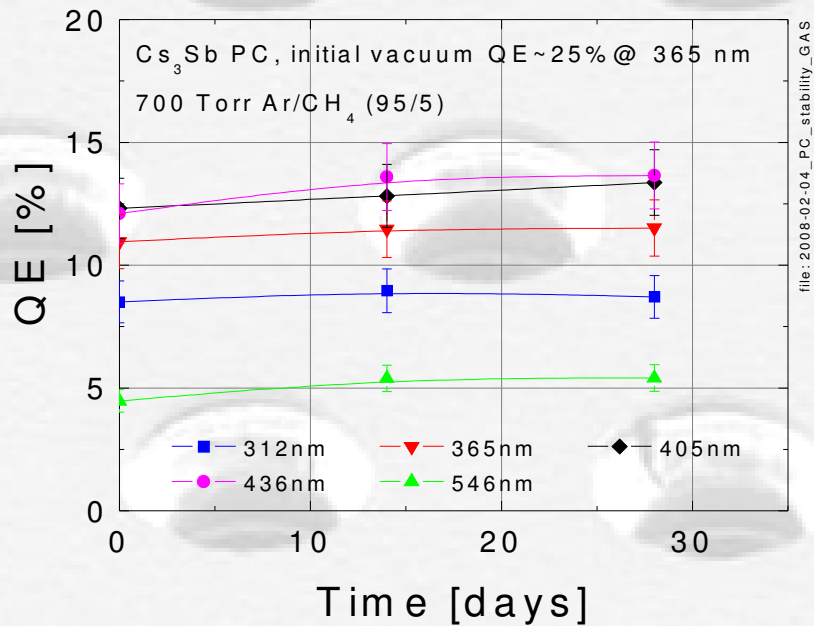

*Optimal field for GPM*

*Higher transmission in other gases, e.g. CH4*

# Long-term photocathode stability in gas

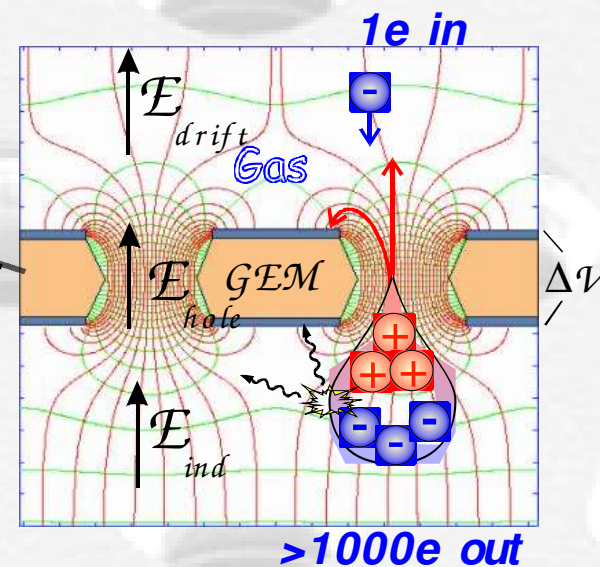

*PC is stable in gas in the large vacuum chamber*

*Expected even better stability for sealed devices*

# Secondary effects in visible-sensitive GPMs

## Gaseous Photo-Multiplier (GPM)

- Main problem: ions & photons →**
- secondary e emission
  - ion/photon feedback pulses
  - gain & performance limitations

Photon feedback is largely reduced  
PC masked by electrode

\*GEM: Gas Electron Multiplier - Sauli, *NIM A* 386, (1997) 531.

## **IBF: Ion Back-Flow Fraction**

*IBF: The average fraction of avalanche-generated ions **back-flowing** to the photocathode*

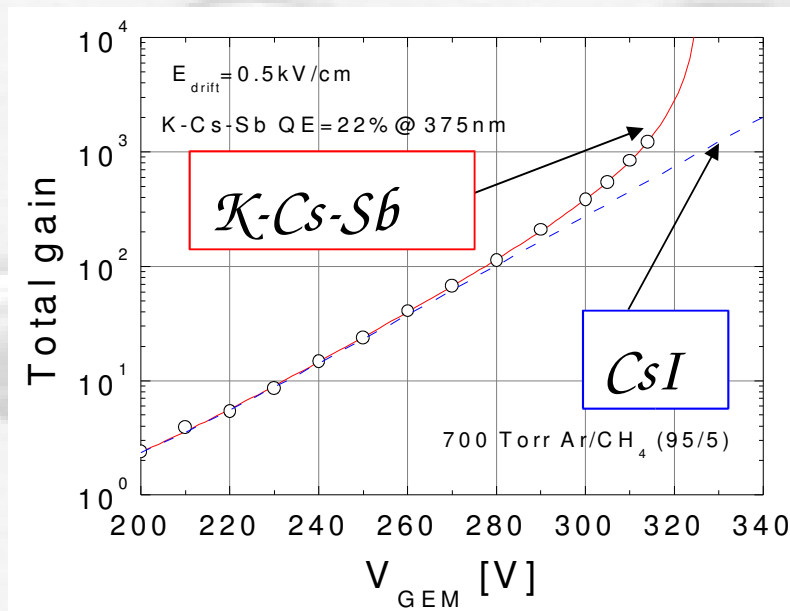

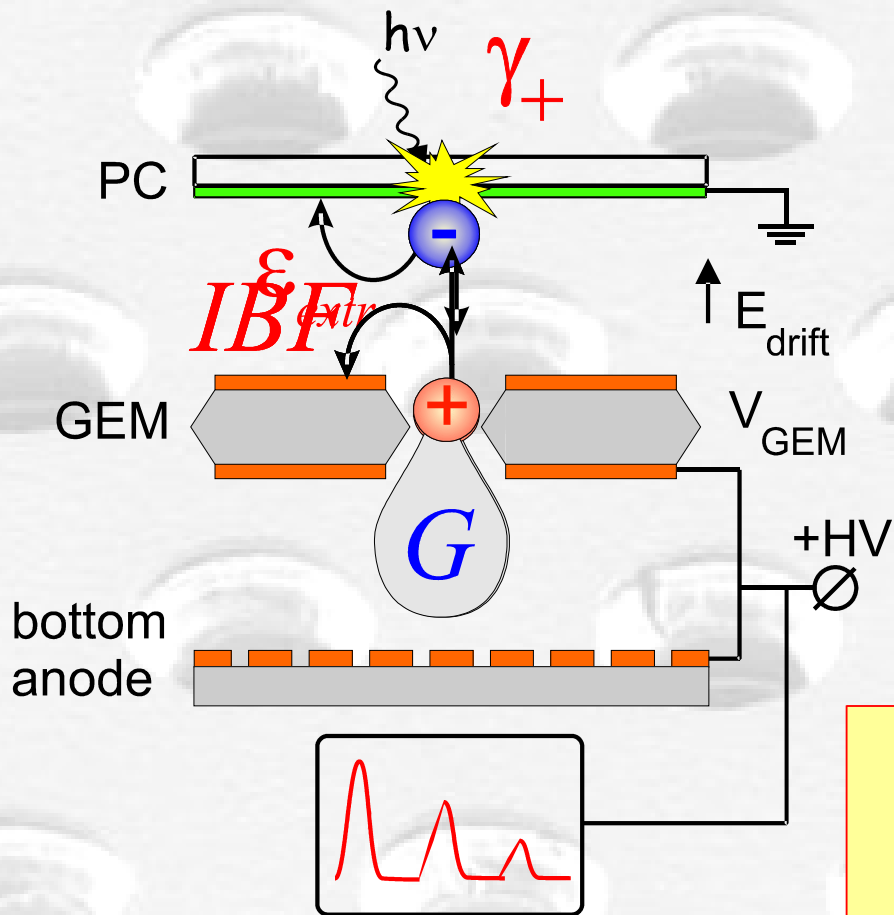

→ **Major efforts to limit ion backflow**

**GATING .1** → operation in “gated-mode” → **deadtime**, trigger  
**NEW e .2 - MULTIPLIERS** → operation in continuous mode  
) **OTHERS** cascaded-GEM, MICROME GAS...&:(

→ **Challenge: BLOCK IONS WITHOUT AFFECTING ELECTRON COLLECTION**

# Visible-sensitive GPM: Ion-feedback development

**K-Cs-Sb, Na-K-Sb, Cs-Sb : Current deviates from exponential  
Max Gain ~ few 100, IBF ~ 10%**

if  $\gamma_+^{eff} \cdot IBF \cdot G < 1$   $\rightarrow$  stable operation of visible sensitive GPM

$G \sim 10^5, \gamma_+^{eff} - ?, IBF - ?$

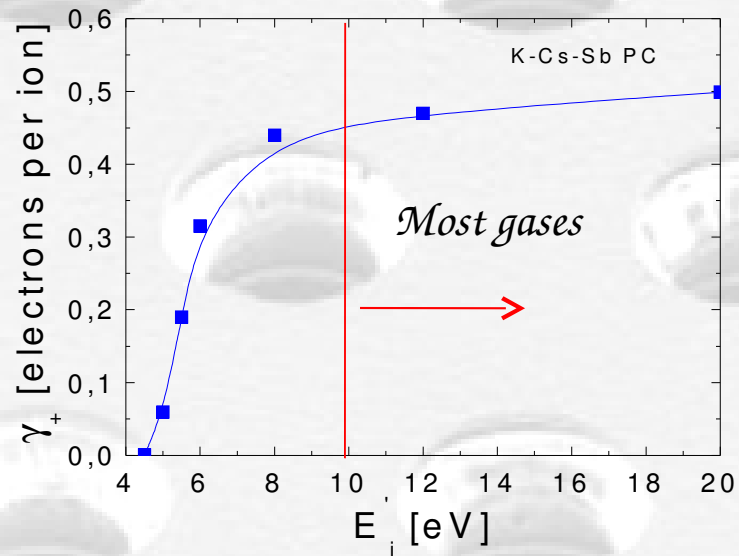

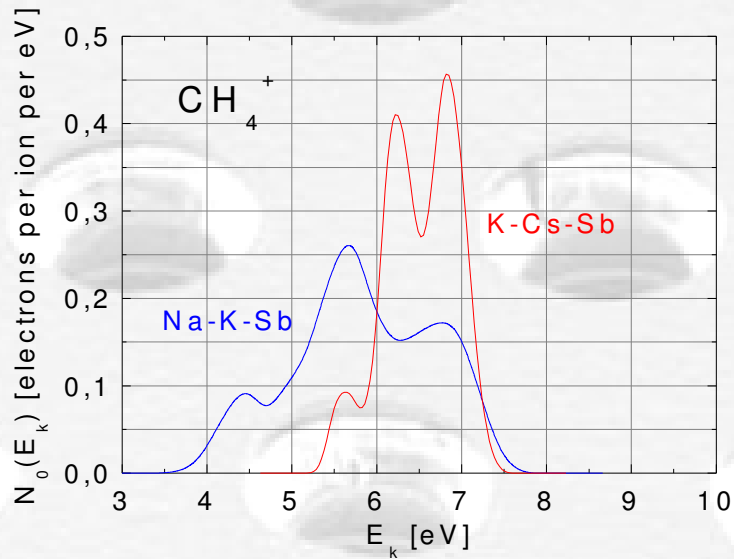

Visible-sensitive gas photomultiplier review:

M. Balcerzyk et al., IEEE Trans. Nucl. Sci. Vol. 50 no. 4 (2003) 847

# Calculation of ion induced secondary emission probability from bi-alkali PCs $\gamma_+^{eff} = \gamma_+ \cdot \epsilon_{extr}$

Auger neutralization + Backscattering

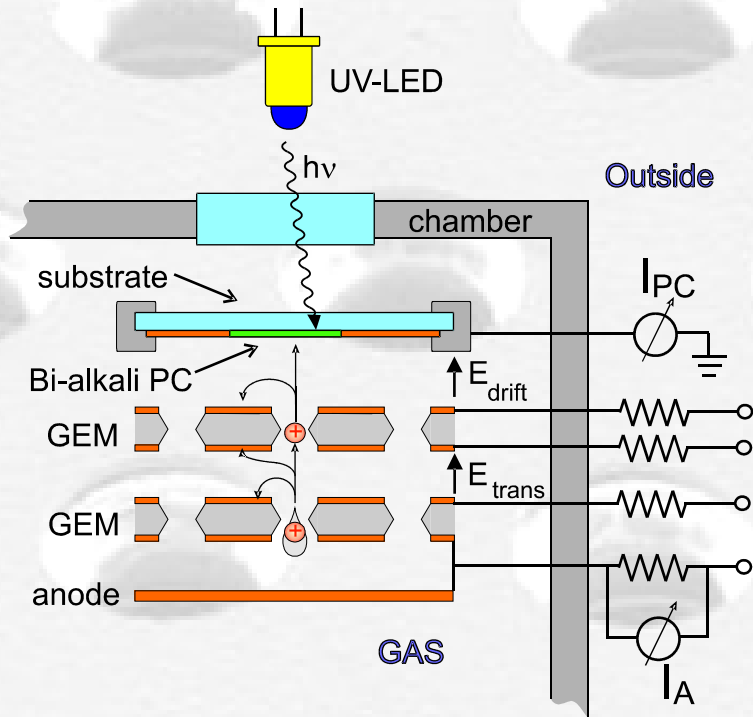

PC	K-Cs-Sb	Na-K-Sb
$\gamma_+^{eff}$	0.027	0.029

A. Lyashenko et al., J. Appl. Phys. (2009) accepted, arXiv:0904.4881

# Measurements of $\gamma_+^{eff} = \gamma_+ \cdot \epsilon_{extr}$

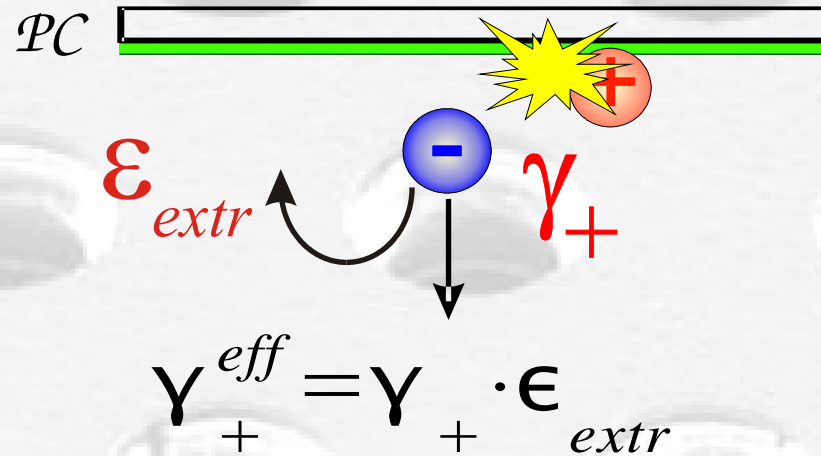

$$G_{meas} = \frac{G}{1 - G \cdot IBF \cdot \gamma_+^{eff}}$$

PC	$K\text{-Cs-Sb}$	$Na\text{-K-Sb}$
$\gamma_+^{eff} (experiment)$	$0.03 \pm 0.01$	$0.02 \pm 0.006$

Effective HSEE from  $\mathcal{K}$ -Cs-Sb and Na- $\mathcal{K}$ -Sb PCs

PC	$\mathcal{K}$ -Cs-Sb	Na- $\mathcal{K}$ -Sb
Ion	$\text{CH}_4^+$	$\text{CH}_4^+$
$\gamma_+^{eff}(\text{exp})$	$0.03 \pm 0.01$	$0.02 \pm 0.006$
$\gamma_+^{eff}(\text{theory})$	$\sim 0.03$	$\sim 0.03$

if  $\gamma_+^{eff} \cdot IBF \cdot G < 1 \rightarrow$  stable operation of visible sensitive GPM

**Ar/CH<sub>4</sub> (95/5),  $\gamma_+^{eff} \sim 0.03$ , Gain  $\sim 10^5 \Rightarrow IBF < 3.3 \cdot 10^{-4}$**

# The Microhole & Strip plate (MHSP)

Two multiplication stages on a single, double-sided, foil

**Strips: multiply charges**

**7 times lower IBF than with cascaded GEMs**

R&D: Weizmann/Coimbra

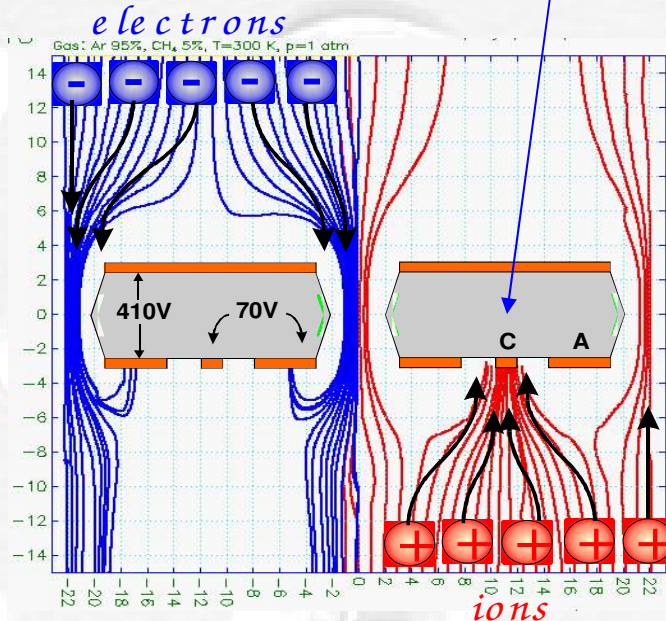

Veloso et al. Rev. Sci. Inst. A 71 (2000) 237.

# Reverse-biased MHSP (R-MHSP) concept

Ions are trapped by negatively biased cathode strips

## R-MHSP

Can trap only ions from successive stages

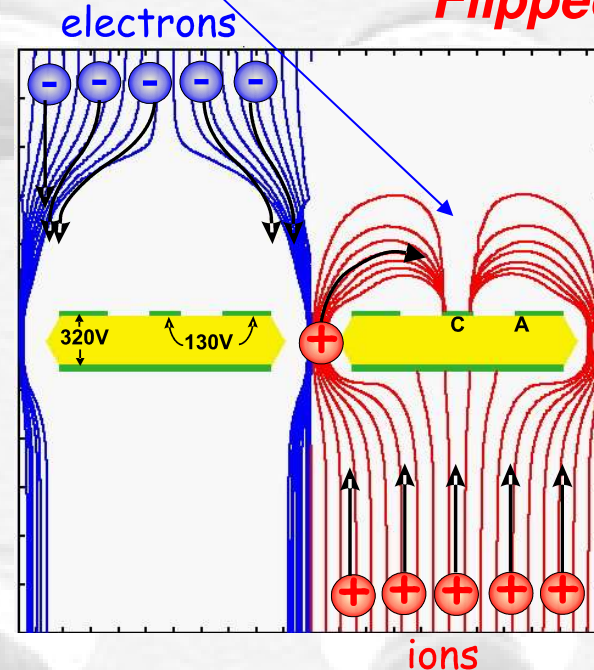

Roth, *NIM A*535 (2004) 330

Breskin et al. *NIM A*553 (2005) 46

Veloso et al. *NIM A*548 (2005) 375

## Strips: collect ions

## Flipped-R-MHSP

Can trap its own ions

Lyashenko et al., *JINRST* (2006) 1 P10004

Lyashenko et al., *JINRST* (2007) 2 P08004

# BEST ION BLOCKING: "COMPOSITE" CASCADED MULTIPLIERS

**1st R-MHSP or F-R-MHSP: ion defocusing (no gain!)**  
**Mid GEMs: gain**  
**Last MHSP: extra gain & ion blocking**

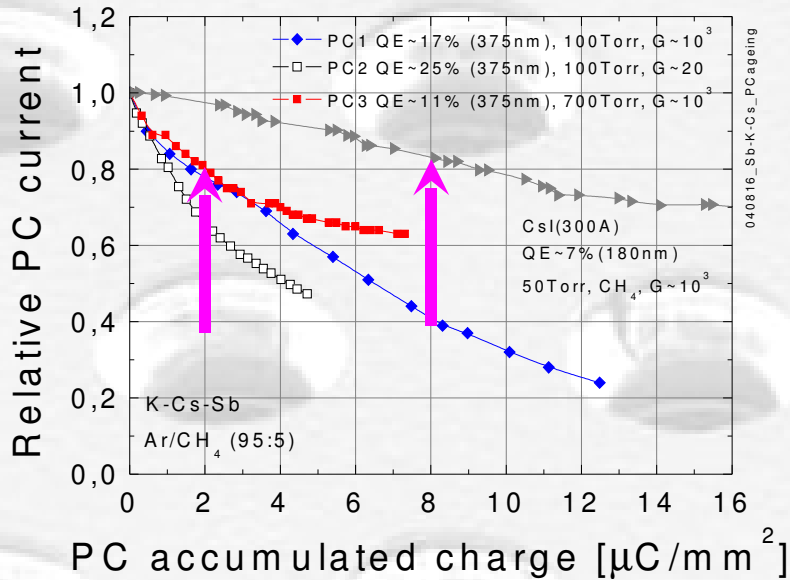

**IBF measured with 100% e-collection efficiency**

**IBF = 3 × 10<sup>-4</sup> @ Gain = 10<sup>5</sup> is 100 times lower than with 3GEMs**

*Lyashenko et al., JINST (2007) 2 P08004*

# K-Sb-Cs PC ageing in avalanche mode

- 20% QE drop @  $2 \mu\text{C}/\text{mm}^2$  ion charge on photocathode:
- only  $\sim 4 \times$  faster drop compared to thin ST CsI ( $\sim 8 \mu\text{C}/\text{mm}^2$ )

Real conditions:  $\text{gain}=10^5$ ;  $\text{IBF}=3 \cdot 10^4$ .

- 20% QE drop **46 years** @  $5 \text{kHz}/\text{mm}^2$  phi. same conditions with a MWPC (IBF $\sim 0.5$ )

→ 3000 times shorter lifetime:  **$\sim 5$  days!**

A. Breskin *et al.* NIM A553 (2005) 46

# Visible-sensitive GPM

*UHV compatible materials*

*Test detector setup*

*Sealed detector*

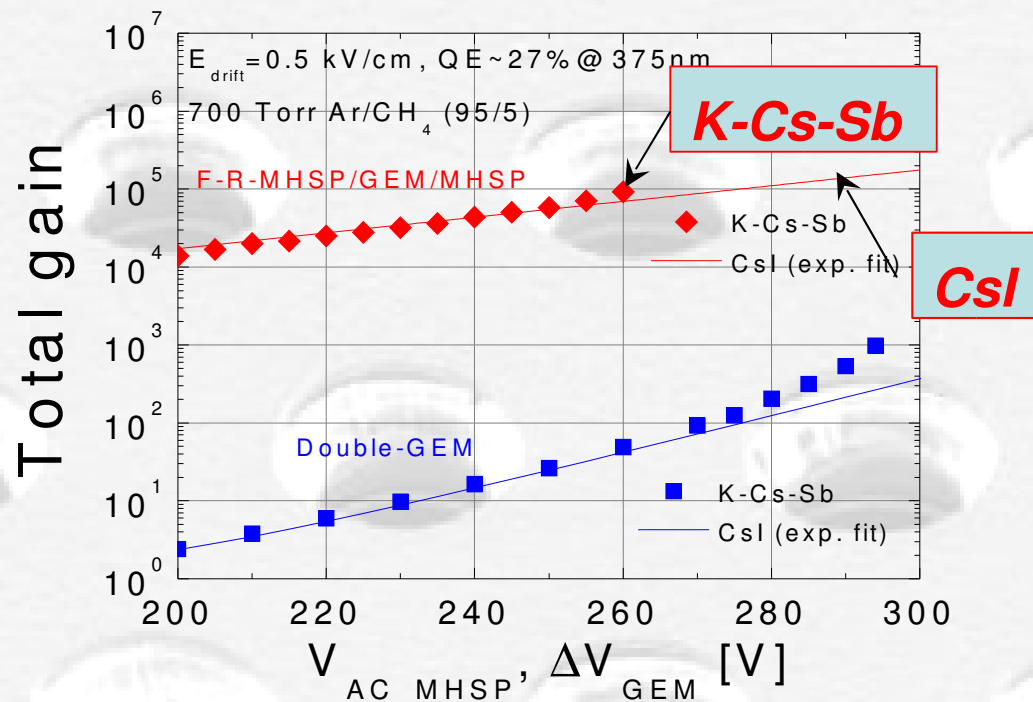

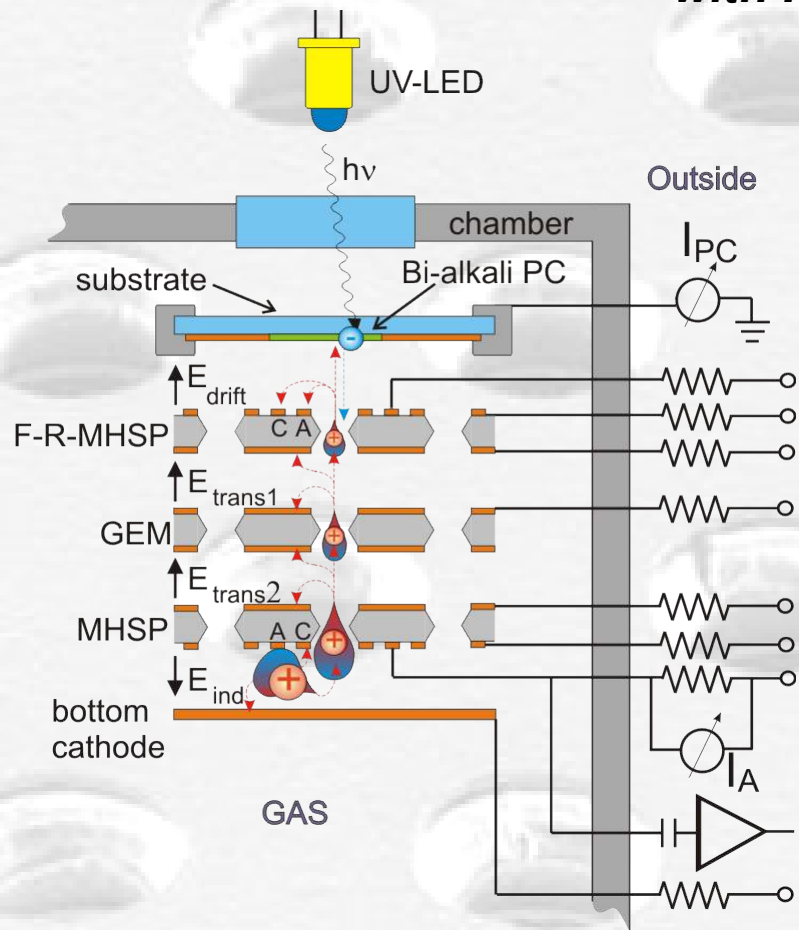

*M. Balcerzyk et al., IEEE Trans. Nucl. Sci. Vol. 50 no. 4 (2003) 847*

# Continuous operation of F-R-MHSP/GEM/MHSP with K-Cs-Sb photocathode

**Gain  $\sim 10^5$  at full photoelectron collection efficiency**

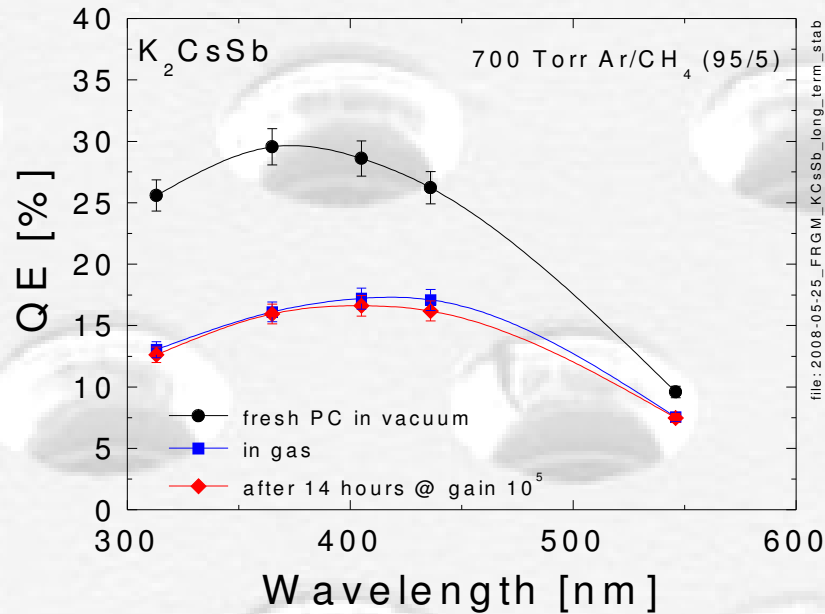

**First evidence of continuous high gain operation of visible-sensitive GPM**

*Lyashenko et al., JINST (2009) 4 P07005*

# Short-term GPM stability

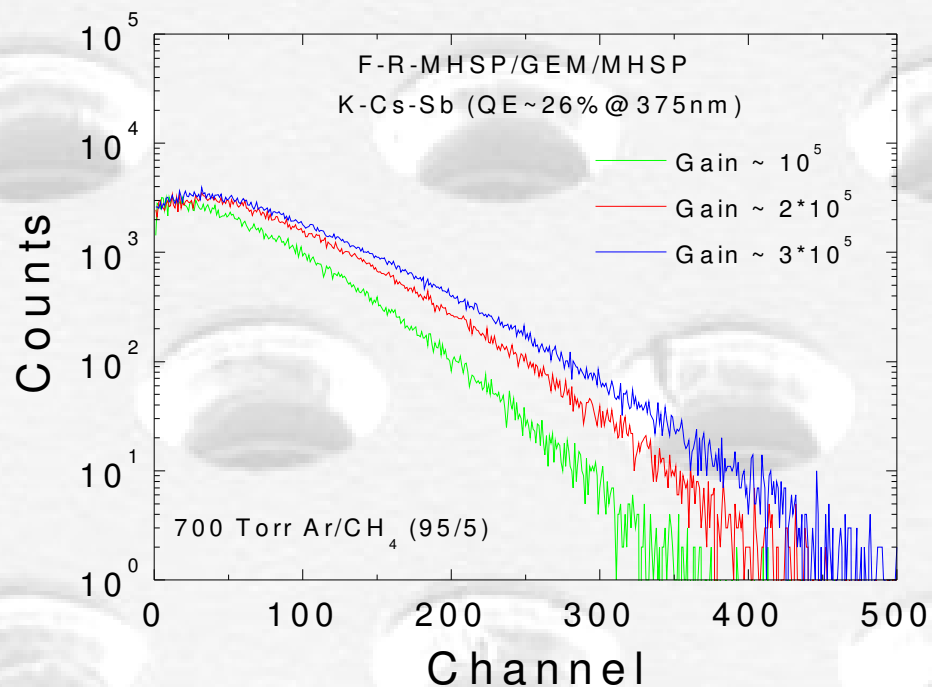

Rate: 12kHz/mm<sup>2</sup> photons

Gain: 10<sup>5</sup>

Total anode charge ~125μC

## Visible-sensitive GPM features

**Single photon sensitivity**  
**No ion-feedback**

**Fast ns pulses**

## Summary

**Alkali-antimonide PCs for GPMs**

**High (>40%) QE values reached**

**Stability in gas verified**

**Probability of IISEE evaluated → Required IBF estimated**

### **MHSP/GEM-based CASCADED MULTIPLIERS**

- **100 times lower IBF than with cascaded GEMs with full efficiency for collecting primary electrons!**
- **Gain  $\sim 10^5$  reached with visible-sensitive K-Cs-Sb PC**
- **Demonstrated stable GPM operation at a gain  $10^5$**
- **Atmospheric pressure operation → Many potential applications in large-area photon detectors: Particle Physics, Medical Imaging, Astroparticle, Military, Bio**

**First evidence of high-gain continuous operation of visible-sensitive GPM**
